

Ciphertext-Ciphertext Equality Argument

1 Preliminaries

Basic notation. For two integers $n < m$, we write $[n, m]$ to denote the set $\{n, n+1, \dots, m\}$. When $n = 1$, we simply write $[m]$ to denote the set $\{1, \dots, m\}$. For any finite set S , we use $x \leftarrow_{\mathbf{R}} S$ to denote the process of sampling an element $x \in S$ uniformly at random. Unless specified otherwise, we use λ to denote the security parameter. We say that an algorithm is efficient if it runs in probabilistic polynomial time in the length of its input. We say that a function $f : \mathbb{N} \rightarrow \mathbb{N}$ is negligible if $f = o(1/n^c)$ for any positive integer $c \in \mathbb{N}$. Throughout the exposition, we use $\text{poly}(\cdot)$ and $\text{negl}(\cdot)$ to denote any polynomial and negligible functions respectively.

1.1 Discrete Log Relation Assumption

The discrete log relation assumption states that given a number of random group elements in \mathbb{G} , no efficient adversary can find a non-trivial relation on these elements.

Definition 1.1 (Discrete Log Relation). Let $\mathbb{G} = \mathbb{G}(\lambda)$ be a group of prime order p . Then the *discrete log relation* assumption on \mathbb{G} states that for any efficient adversary \mathcal{A} and $n \geq 2$, there exists a negligible function $\text{negl}(\lambda)$ such that

$$\Pr \left[\mathcal{A}(G_1, \dots, G_n) \rightarrow a_1, \dots, a_n \in \mathbb{Z}_p : \exists a_i \neq 0 \wedge \sum_{i \in [n]} a_i \cdot G = 0 \right] = \text{negl}(\lambda),$$

where $G_1, \dots, G_n \leftarrow_{\mathbf{R}} \mathbb{G}$.

1.2 Rewinding Lemma

To prove security, we make use of the rewinding lemma. For the purpose of this document, we do not require the rewinding lemma in its full generality and therefore, we rely on the following simple variant from Boneh and Shoup [1].

Lemma 1.2 (Rewinding Lemma). *Let S and T be finite, non-empty sets, and let $f : S \times T \rightarrow \{0, 1\}$ be a function. Let X , Y , and Y' be mutually independent random variables, where X takes values in the set S , and Y , Y' are each uniformly distributed over T . Let $\varepsilon = \Pr[f(X, Y) = 1]$ and $N = |T|$. Then*

$$\Pr[f(X, Y) = 1 \wedge f(X, Y') = 1 \wedge Y \neq Y'] \geq \varepsilon^2 - \varepsilon/N.$$

2 Zero-Knowledge Argument Definitions

In full generality, zero-knowledge argument systems can be defined with respect to any class of decidable languages. However, to simplify the presentation, we define argument systems with respect to CRS-dependent languages. Specifically, let $\mathcal{R} \subset \{0, 1\}^* \times \{0, 1\}^* \times \{0, 1\}^*$ be an efficiently decidable ternary relation. Then a CRS-dependent language for a string $\rho \in \{0, 1\}^*$ is defined as

$$\mathcal{L}_\rho = \{u \mid \exists w : (\rho, u, w) \in \mathcal{R}\}.$$

We generally refer to ρ as the common reference string, u as the instance of the language, and w as the witness for u .

For a class of CRS-dependent languages, an argument system consists of the following algorithms.

Definition 2.1 (Argument System). A non-interactive argument system Π_{AS} for a CRS-dependent relation \mathcal{R} consists of a tuple of efficient algorithms (**Setup**, **Prove**, **Verify**) with the following syntax:

- **Setup**(1^λ) $\rightarrow \rho$: On input the security parameter λ , the setup algorithm returns a common reference string ρ .
- $\mathcal{P}(\sigma, u, w)$: The prover \mathcal{P} is an interactive algorithm that takes in as input a common reference string σ , instance u , and witness w . It interacts with the verifier \mathcal{V} according to the specification of the protocol.
- $\mathcal{V}(\sigma, u)$: The verifier \mathcal{V} is an interactive algorithm that takes in as input a common reference string ρ and an instance x . It interacts with the prover \mathcal{P} in the protocol and in the end, it either accepts (returns 1) or rejects (returns 0) the instance x .

We use $\langle \mathcal{P}(\rho, u, w), \mathcal{V}(\rho, u) \rangle = 1$ to denote the event that the verifier \mathcal{V} accepts the instance of the protocol. We use $\langle \mathcal{P}(\rho, u, w), \mathcal{V}(\rho, u) \rangle \rightarrow \text{tr}$ to denote the communication transcript between the prover \mathcal{P} and verifier \mathcal{V} during a specific execution of the protocol.

An argument system must satisfy a correctness and two security properties. The correctness property of an argument system is generally referred to as *completeness*. It states that if the prover \mathcal{P} takes in as input a valid instance-witness tuple $(\rho, u, w) \in \mathcal{R}$ and follows the protocol specification, then it must be able to convince the verifier to accept.

Definition 2.2 (Completeness). Let Π_{AS} be a proof system for a relation \mathcal{R} . Then we say that Π_{AS} satisfies perfect completeness if for any $(u, w) \in \mathcal{R}$, we have

$$\Pr [\langle \mathcal{P}(\rho, u, w), \mathcal{V}(\rho, u) \rangle = 1] = 1,$$

where $\rho \leftarrow \text{Setup}(1^\lambda)$.

The first security property that an argument system must satisfy is *soundness*, which can be defined in a number of ways. In this work, we work with *computational witness-extended emulation* as presented in Bulletproofs [2].

Definition 2.3 (Soundness [3, 4, 2]). Let Π_{AS} be a proof system for a relation \mathcal{R} . Then we say that Π_{AS} satisfies *witness-extended emulation* soundness if for all deterministic polynomial time \mathcal{P}^* ,

there exists an efficient emulator \mathcal{E} such that for all efficient adversaries $\mathcal{A} = (\mathcal{A}_1, \mathcal{A}_2)$, there exists a negligible function $\text{negl}(\lambda)$ such that

$$\left| \Pr \left[\mathcal{A}_2(\text{tr}) = 1 \mid \begin{array}{l} \rho \leftarrow \text{Setup}(1^\lambda), (u, \text{st}) \leftarrow \mathcal{A}_1(\rho), \\ \text{tr} \leftarrow \langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle \end{array} \right] - \Pr \left[\mathcal{A}_2(\text{tr}) = 1 \wedge (\text{tr accepting} \Rightarrow (\rho, u, w) \in \mathcal{R}) \mid \begin{array}{l} \rho \leftarrow \text{Setup}(1^\lambda), \\ (u, \text{st}) \leftarrow \mathcal{A}_1(\rho), \\ (\text{tr}, w) \leftarrow \mathcal{E}^\mathcal{O}(\rho, u) \end{array} \right] \right| = \text{negl}(\lambda),$$

where the oracle is defined as $\mathcal{O} = \langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$. The oracle \mathcal{O} allows the emulator \mathcal{E} to rewind the protocol to a specific point and resume the protocol after reprogramming the verifier with fresh randomness.

Traditionally, the soundness condition for an argument system of knowledge requires that there exists an extractor that can use its rewinding capability to extract a valid witness from any accepting transcript of the protocol that is produced by a dishonest prover \mathcal{P}^* . The witness-extended emulation strengthens this traditional definition by requiring that the extractor (emulator) not only successfully extracts a valid witness, but also produces (emulates) a valid transcript of the protocol for which the verifier accepts. The value st in the definition above can be viewed as the internal state of \mathcal{P}^* , which can also be its randomness.

The second security property that we require from an argument system is the zero-knowledge property. All argument systems that we rely on in the **ZK-Token** program are public coin protocols that we ultimately convert into a non-interactive protocol. Therefore, we rely on the standard zero-knowledge property against honest verifiers.

Definition 2.4 (Zero-Knowledge). Let Π_{AS} be a proof system for a relation \mathcal{R} . Then we say that Π_{AS} satisfies *honest verifier* zero-knowledge if there exists an efficient simulator \mathcal{S} such that for all efficient adversaries $\mathcal{A} = (\mathcal{A}_1, \mathcal{A}_2)$, we have

$$\begin{aligned} & \Pr \left[(\rho, u, w) \in \mathcal{R} \wedge \mathcal{A}_1(\text{tr}) = 1 \mid \begin{array}{l} \rho \leftarrow \text{Setup}(1^\lambda), (u, w, \tau) \leftarrow \mathcal{A}_2(\rho), \\ \text{tr} \leftarrow \langle \mathcal{P}(\rho, u, w), \mathcal{V}(\rho, u; \tau) \rangle \end{array} \right] \\ &= \Pr \left[(\rho, u, w) \in \mathcal{R} \wedge \mathcal{A}_1(\text{tr}) = 1 \mid \begin{array}{l} \rho \leftarrow \text{Setup}(1^\lambda), \\ (u, w, \tau) \leftarrow \mathcal{A}_2(\rho), \\ \text{tr} \leftarrow \mathcal{S}(u, \tau) \end{array} \right], \end{aligned}$$

where ρ is the public coin randomness used by the verifier.

3 Argument System Description

At the start of the protocol, the prover and verifier have access to two twisted ElGamal ciphertexts. The prover's goal is to convince the verifier that it knows a secret key for the first ciphertext and a Pedersen opening (encryption randomness) for the second ciphertext. Formally, the language is captured by the protocol is specified as follows:

$$\mathcal{L}_{G,H}^{\text{eq-ctxt}} = \left\{ \begin{array}{l} u = (P_0, C_0, D_0, P_1, C_1, D_1) \in \mathbb{G}^6, \\ w = (s, x, r) \in \mathbb{Z}_p^3 \end{array} \mid \begin{array}{l} s \cdot P_0 = H \wedge C_0 - s \cdot D_0 = x \cdot G \\ \wedge C_1 = r \cdot P_1 \wedge C_1 = x \cdot G + r \cdot H \end{array} \right\}.$$

The language $\mathcal{L}_{G,H}^{\text{eq-ctxt}}$ is specified by two group elements $G, H \in \mathbb{G}$ that define the ElGamal encryption. The group elements P_0 and P_1 correspond to public keys pertaining to the first and second ciphertexts that are represented by a pair of elements $\text{ct}_0 = (C_0, D_0)$ and $\text{ct}_1 = (C_1, D_1)$. The prover has access to the decryption key for the first ciphertext s and the randomness that was used to generate the second ciphertext r . The relation holds true if $\text{ct}_0 = (C_0, D_0)$ and $\text{ct}_1 = (C_1, D_1)$ encrypt the same message x . The argument system for the language $\mathcal{L}_{G,H}^{\text{eq-ctxt}}$ is specified as follows:

The equality protocol follows a standard sigma protocol structure where the prover first samples random field elements y_s, y_x, y_r . It then commits to these elements by sending $Y_0 = y_s \cdot P_{\text{EG}}$, $Y_1 = y_x \cdot G + y_s \cdot D_{\text{EG}}$, $Y_2 = y_x \cdot G + y_r \cdot H$, and $Y_3 = y_r \cdot P_1$. Upon receiving a random challenge c , it provides the verifier with the masked secret key $z_s = c \cdot s + y_s$, $z_x = c \cdot x + y_x$, and $z_r = c \cdot r + y_r$. Finally, the verifier tests the four relations associated with $\mathcal{L}_{G,H}^{\text{eq-ctxt}}$ using the masked secret key z , and the committed values Y_0, Y_1, Y_2 , and Y_3 .

The equality argument system above satisfies all the correctness and security properties that are specified in Section 2. We formally state these properties in the following theorems.

Theorem 3.1 (Completeness). *The ciphertext-ciphertext equality argument satisfies completeness 2.2.*

Theorem 3.2 (Soundness). *Suppose that \mathbb{G} is a prime order group for which the discrete log relation assumption (Definition 1.1) holds. Then the ciphertext-ciphertext argument satisfies witness-extended emulation soundness 2.3.*

Theorem 3.3 (Zero-Knowledge). *The ciphertext-ciphertext equality argument satisfies perfect honest verifier zero-knowledge 2.4.*

4 Proof of Security

4.1 Proof of Theorem 3.1

To prove completeness, let us fix any valid instance and witness for $\mathcal{L}_{G,H}^{\text{eq-ctxt}}$: $P_0, C_0, D_0, P_1, C_1, D_1 \in \mathbb{G}$ and $s, x, r \in \mathbb{Z}_p$ such that

- $s \cdot P_0 = H$
- $C_0 - s \cdot D_0 = x \cdot G$
- $C_1 = x \cdot G + r \cdot H$
- $D_1 = r \cdot P_1$

Let y_s, y_x, y_r and c be any elements in \mathbb{Z}_p , and let

- $Y_0 = y_s \cdot P_0, Y_1 = y_x \cdot G + y_s \cdot D_0, Y_2 = y_x \cdot G + y_r \cdot H, Y_3 = y_r \cdot P_1$
- $z_s = c \cdot s + y_s, z_x = c \cdot x + y_x, \text{ and } z_r = c \cdot r + y_r$

in an execution of the protocol. Then we have

$$\begin{aligned} z_s \cdot P_0 &= (c \cdot s + y_s) \cdot P_0 \\ &= c \cdot (s \cdot P_0) + y_s \cdot P_0 \\ &= c \cdot H + Y_0 \end{aligned}$$

$$\begin{aligned} z_x \cdot G + z_s \cdot D_0 &= (c \cdot x + y_x) \cdot G + (c \cdot s + y_s) \cdot D_0 \\ &= c \cdot (x \cdot G + s \cdot D_0) + (y_x \cdot G + y_s \cdot D_0) \\ &= c \cdot C_0 + Y_1 \end{aligned}$$

$$\begin{aligned} z_x \cdot G + z_r \cdot H &= (c \cdot x + y_x) \cdot G + (c \cdot r + y_r) \cdot H \\ &= c \cdot (x \cdot G + r \cdot H) + (y_x \cdot G + y_r \cdot H) \\ &= c \cdot C_1 + Y_2 \end{aligned}$$

$$\begin{aligned} z_r \cdot P_1 &= (c \cdot r + y_r) \cdot P_1 \\ &= c \cdot r \cdot P_1 + y_r \cdot H \\ &= c \cdot D_1 + Y_3 \end{aligned}$$

As all the algebraic relations that the verifier checks hold, the proof is always accepted. Completeness follows.

4.2 Proof of Theorem 3.2

To prove soundness, we construct an emulator \mathcal{E} that has oracle access to any malicious prover \mathcal{P}^* and extracts a valid witness by rewinding \mathcal{P}^* and simulating two execution of the equality protocol with an honest verifier \mathcal{V} .

Let $(P_0, C_0, D_0, P_1, C_1, D_1)$ be an instance of the language $\mathcal{L}_{G,H}^{\text{eq-ctxt}}$. We construct an emulator \mathcal{E} that uses \mathcal{P}^* to extract a valid witness as follows:

- The emulator \mathcal{E} first executes $\langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$ to produce a transcript $\text{tr} = (Y_0, Y_1, Y_2, Y_3, c, z_s, z_x, z_r)$.
- Then, it rewinds the protocol to the point where the verifier \mathcal{V} samples a random $c \leftarrow_{\mathcal{R}} \mathbb{Z}_p$. It programs \mathcal{V} with fresh randomness such that \mathcal{V} generates a new $c' \leftarrow \mathbb{Z}_p$ independently of the previous execution of the protocol.
- The emulator completes the second execution of $\langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$, producing a new transcript $\text{tr} = (Y_0, Y_1, Y_2, Y_3, c, z'_s, z'_x, z'_r)$.
- If $c - c' = 0$, then the emulator aborts and returns \perp . Otherwise, it computes
 - $s \leftarrow (z_s - z'_s)/(c - c')$
 - $x \leftarrow (z_x - z'_x)/(c - c')$
 - $r \leftarrow (z_r - z'_r)/(c - c')$

and returns (s, x, r) as the witness.

To complete the proof, we first bound the probability that \mathcal{E} does not abort at the end of the two executions of $\langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$. Then, we show that if \mathcal{E} does not abort, then the extracted witness (s, x, r) is valid.

Abort probability. The emulator \mathcal{E} aborts only when $c = c'$, which is dependent on the probability that \mathcal{P}^* successfully convinces \mathcal{V} at the end of the protocol. Let $\varepsilon_{\mathcal{P}^*}$ be the probability that \mathcal{P}^* successfully convinces \mathcal{V} in $\langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$. We bound the probability that $c = c'$ with $\varepsilon_{\mathcal{P}^*}$ using the rewinding lemma 1.2. Specifically, let us define the following random variables:

- Let X be the elements (Y_0, Y_1, Y_2, Y_3) in the transcript of an execution of $\langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$.
- Let Y and Y' be the values c and c' respectively in the two executions of $\langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$.
- Let Z and Z' be the values (z_s, z_x, z_r) and (z'_s, z'_x, z'_r) respectively in the two executions of $\langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$.
- Let $f(\text{tr}) \rightarrow \{0, 1\}$ be the protocol verification function that returns 1 if tr is an accepting transcript and 0 otherwise.

Then, the rewinding lemma states that

$$\Pr [f(X, Y, Z) = 1 \wedge f(X, Y', Z') = 1 \wedge Y \neq Y'] \geq \varepsilon_{\mathcal{P}^*}^2 - \varepsilon_{\mathcal{P}^*}/p.$$

By assumption, we have $1/p = \text{negl}(\lambda)$. Therefore, if $\varepsilon_{\mathcal{P}^*}$ is non-negligible, then the probability that \mathcal{E} does not abort at the end of the two excusions of $\langle \mathcal{P}^*(\rho, u, \text{st}), \mathcal{V}(\rho, u) \rangle$ is non-negligible.

Witness validity. Now assume that the two executions of $\langle \mathcal{P}(\rho, u, w), \mathcal{V}(\rho, u) \rangle$ returns two accepting transcripts $\text{tr} = (Y_0, Y_1, Y_2, c, z_s, z_x, z_r)$, $\text{tr}' = (Y_0, Y_1, Y_2, c', z'_s, z'_x, z'_r)$, and that \mathcal{E} does not abort and returns

- $s \leftarrow (z_s - z'_s)/(c - c')$
- $x \leftarrow (z_x - z'_x)/(c - c')$
- $r \leftarrow (z_r - z'_r)/(c - c')$

Since tr and tr' are accepting transcripts, we have

$$z_s \cdot P_0 = c \cdot H + Y_0,$$

$$z'_s \cdot P_0 = c' \cdot H + Y_0,$$

This means that $(z_s - z'_s) \cdot P_0 = (c - c') \cdot H$ and hence, $s \cdot P_0 = H$. Similarly, we have

$$z_x \cdot G + z_s \cdot D_0 = c \cdot C_0 + Y_1,$$

$$z'_x \cdot G + z'_s \cdot D_0 = c' \cdot C_0 + Y_1,$$

This means that $(z_x - z'_x) \cdot G + (z_s - z'_s) \cdot D_0 = (c - c') \cdot C_0$ and hence, $x \cdot G + s \cdot D_0 = C_0$. We have

$$z_x \cdot G + z_r \cdot H = c \cdot C_1 + Y_2,$$

$$z'_x \cdot G + z'_r \cdot H = c' \cdot C_1 + Y_2,$$

which means that $(z_x - z'_x) \cdot G + (z_r - z'_r) \cdot H = (c - c') \cdot C_1$ and hence, $x \cdot G + r \cdot H = C_1$. Finally, we have

$$z_r \cdot P_1 = c \cdot D_1 + Y_3,$$

$$z'_r \cdot P_1 = c' \cdot D_1 + Y_3,$$

which means that $(z_r - z'_r) \cdot P_1 = (c - c') \cdot D_1$ and hence $r \cdot P_1 = D_1$.

We have shown that if \mathcal{P}^* successfully convinces the verifier \mathcal{V} for an instance $x = (P_0, C_0, D_0, P_1, C_1, D_1)$ with non-negligible probability, then the emulator \mathcal{E} successfully extracts a valid witness (s, x, r) . This completes the proof of soundness.

4.3 Proof of Theorem 3.3

Fix any elements $P_0, C_0, D_0, C_1, D_1 \in G$ and $s, x, r \in \mathbb{Z}_p$ that satisfy the witness relation of $\mathcal{L}_{G,H}^{\text{eq-ctxt}}$. Let $\text{tr}^* = (Y_0^*, Y_1^*, Y_2^*, Y_3^*, c^*, z_s^*, z_x^*, z_r^*)$ be any accepting transcript. By the specification of the protocol, the probability that an honest execution of the protocol by the prover and the verifier results in the transcript tr^* is as follows:

$$\Pr [\langle \mathcal{P}(\rho, u, w), \mathcal{V}(\rho, u) \rangle \rightarrow \text{tr} \wedge \text{tr} = \text{tr}^*] = 1/p^5.$$

To prove zero-knowledge, we define a simulator \mathcal{S} that produces such distribution without knowledge of a valid witness s, x , and r .

$\mathcal{S}(P_0, C_0, D_0, P_1, C_1, D_1)$:

1. Sample $c, z_s, z_x, z_r \xleftarrow{\mathcal{R}} \mathbb{Z}_p$

2. Set $Y_0 = z_x \cdot P_0 - c \cdot H$
3. Set $Y_1 = z_x \cdot G + z_s \cdot D_0 - c \cdot C_0$
4. Set $Y_2 = z_x \cdot G + z_r \cdot H - c \cdot C_0$
5. Set $Y_3 = z_r \cdot P_1 - c \cdot D_1$
6. Return $\text{tr} = (Y_0, Y_1, Y_2, Y_3, c, z_s, z_x, z_r)$

The simulator \mathcal{S} returns a transcript that is uniformly random given that

- $z_x \cdot P_0 = c \cdot H + Y_0$,
- $z_x \cdot G + z_s \cdot D_0 = c \cdot C_0 + Y_1$,
- $z_x \cdot G + z_r \cdot H = c \cdot C_1 + Y_2$.
- $z_r \cdot P_1 = c \cdot D_1 + Y_3$.

As the variables Y_0, Y_1, Y_2 , and Y_3 are completely determined by c, z_s, z_x, z_r , we have

$$\Pr[\mathcal{S}(P_0, C_0, D_0, P_1, C_1, D_1) \rightarrow \text{tr} \wedge \text{tr} = \text{tr}^*] = 1/p^5,$$

for any fixed transcript tr^* . Zero-knowledge follows.
